Engineering fixture - synthetic paper

SYNTHETIC EXAMPLE ONLY. Not a published paper or a real experiment.

1. Research question

This fixture asks whether model A has lower prediction error than model B on synthetic two-dimensional fields.

2. Methods and data

Both models evaluate the same 8 independent synthetic fields, with paired comparisons by field. Grid points within a field are technical measurements, not independent experimental units.

Training, validation and final test fields are separated by source. Both models use the same splits and tuning budget. The scope is restricted to this synthetic field distribution.

3. Illustrative results

Illustrative mean relative errors are 0.12 for model A and 0.15 for model B. These numbers are authored fixture values, not observed scientific evidence.

4. Limitations

No observed variance or confidence interval is provided. No scientific experiment was executed. This fixture does not establish a causal effect or out-of-distribution performance.

5. Reproduction information still needed

A real study needs a traceable dataset version, code and configuration, independent-unit verification and pilot variability. A sample-size or power guarantee cannot be inferred from this fixture.

This fixture tests PDF extraction and grounded interpretation, not scientific validity.
